

## Building the Login API

In this exercise, you'll create a login endpoint that accepts a user's credentials and checks if they're valid. This is your first step toward implementing authentication. For now, we'll keep things simple—your endpoint should return an empty response with the right status to indicate if credentials are correct. We'll handle JWTs in a later lesson.

Example Request:

```
POST /auth/login

{
  "email": "user1@domain.com",
  "password": "123456"
}
```

Example Response:

- If credentials are invalid, return 401 UNAUTHORIZED.
- If successful, return 200 OK.
